

AgentPay

Instant micropayment rails letting AI agents pay each other for data and compute on Solana

The Problem & Our Solution

AI agents can now think and act autonomously, but they still can't pay each other without a human clicking approve.

- Agents increasingly call paid APIs: search, data, compute, other agents
- Current billing needs human-in-the-loop: API keys, invoices, manual approval
- This blocks true agent-to-agent commerce at machine speed
- AgentPay: Solana-based middleware with a 402-style pay-per-call flow
- Any API returns a price; the calling agent auto-pays in USDC and gets the response

How It Works

A lightweight 402 challenge-response wraps any REST API with a Solana payroll, settled in under a second.

- User flow: agent calls endpoint, gets 402 + price, pays, retries, receives data
- Agent wallet holds programmable spend limits and allowlists for safety
- Architecture: Rust/Anchor middleware, Node.js SDK, Next.js dashboard, Helius RPC
- On-chain: USDC/SOL payment transaction plus a minted receipt/invoice NFT per call
- Demo marketplace: agents buying web search, image-gen, and data feeds from each other

Built with

Solana, Rust, Anchor, Next.js, Solana Pay, USDC SPL Token, Node.js SDK

Why Now & What's Next

Agentic AI is exploding in 2025, and machine-to-machine payment rails are a widely cited missing piece.

- Solana's speed and low cost make it a natural settlement layer for micropayments
- Next: native integrations with agent frameworks like LangChain and CrewAI
- Next: streaming/metered payments for long-running compute jobs
- Next: public marketplace with reputation and dispute resolution
- Built at the Colosseum hackathon as a protocol + SDK for agent commerce
